# Key takeaway

- ❑ Sensitivity experiments to ICM initial conditions (spin-up time requirements)
  - ✓ Three-yr spin-up was found to be sufficient for the MBM to reach equilibrium (ICM)
  
- ❑ Sensitivity experiments for riverine nutrient loadings: **first results**
  - ✓ In preparation for WIP scenarios
  - ✓ Tested NO<sub>3</sub>/NH<sub>4</sub>/PO<sub>4</sub>
  - ✓ Response of hypoxia to riverine nutrient changes

# Sensitivity Experiments to ICM Initial Conditions

- ❑ Two ICM offline experiments are assessed in long-term simulations (1985-2020)

## ICM (offline)

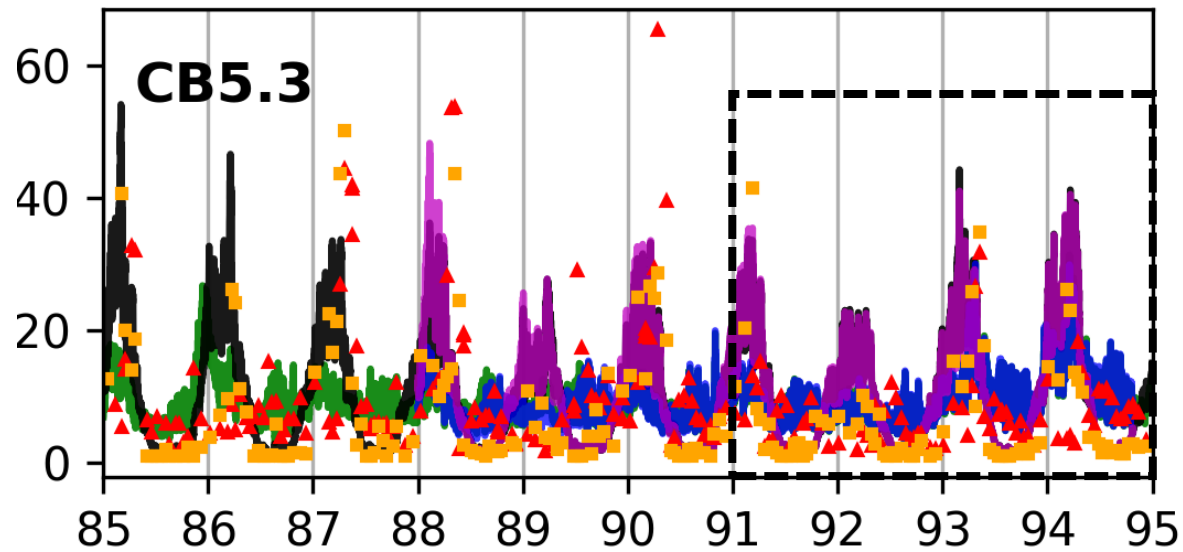

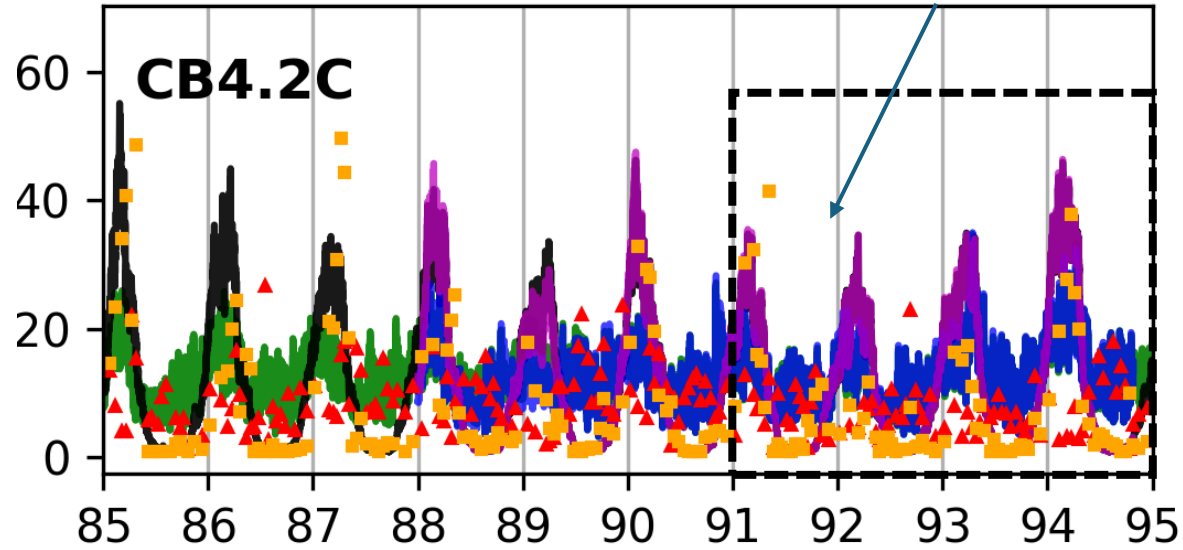

- Same initial condition (**hotstart.nc in 1991**)
- Same ICM parameters (icm.nml)
- Time-dependent boundary inputs catered to each experiment

**How long do the two simulations take to converge?**

# Sensitivity Exps to ICM Initial Conditions: Chl-A

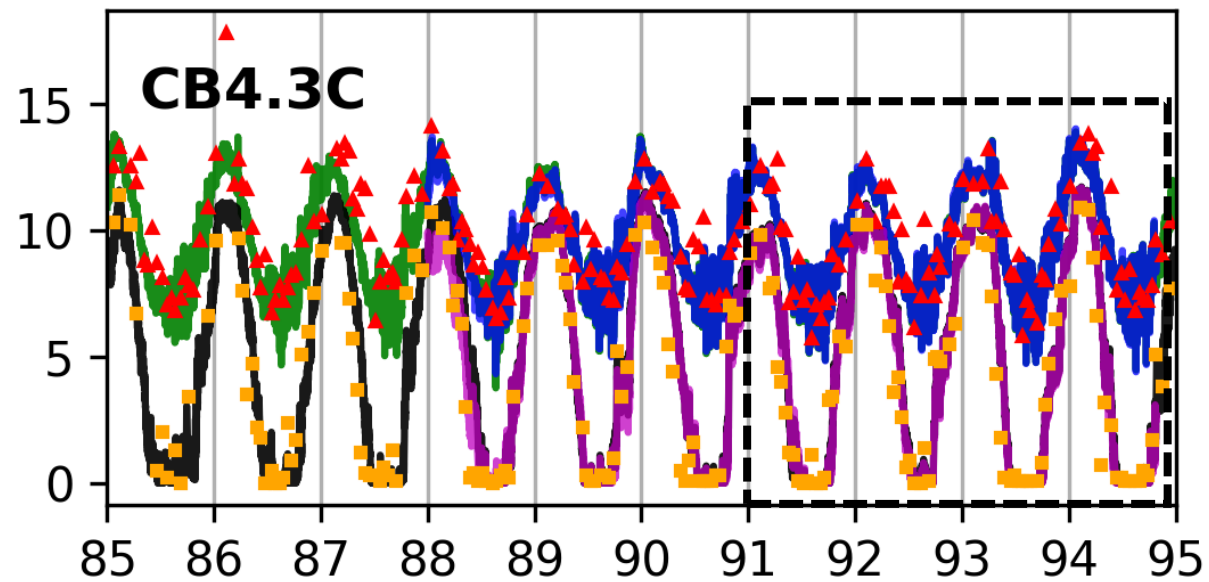

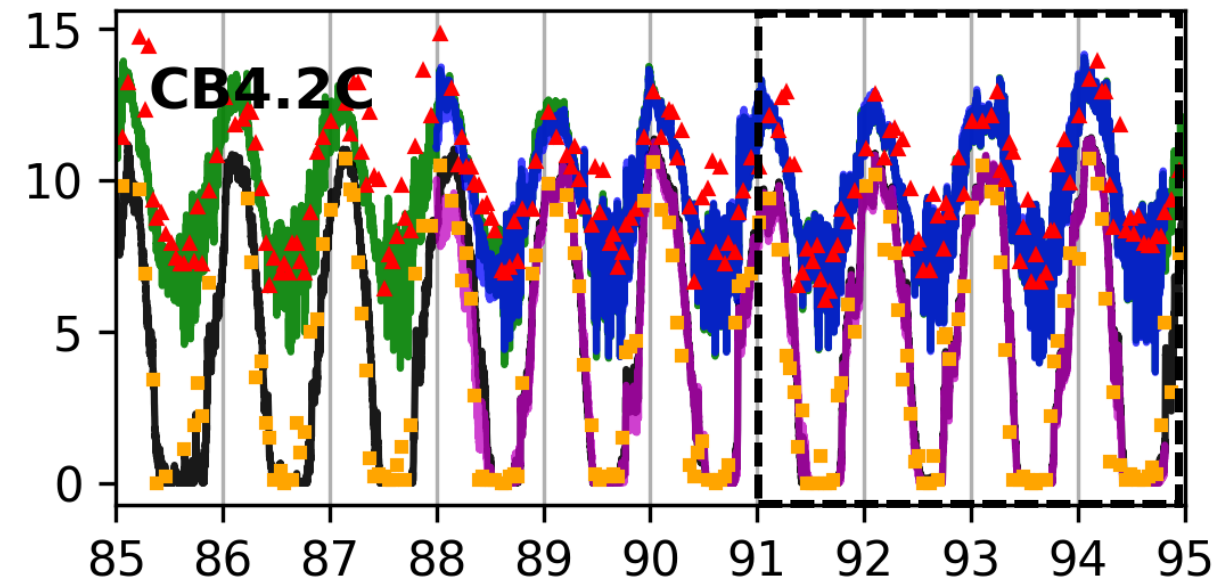

Surface (RUN15a5) Surface (RUN15a6) Surface (OBS)  
Bottom (RUN15a5) Bottom (RUN15a6) Bottom (OBS)

CHLA converged after ~3 yrs

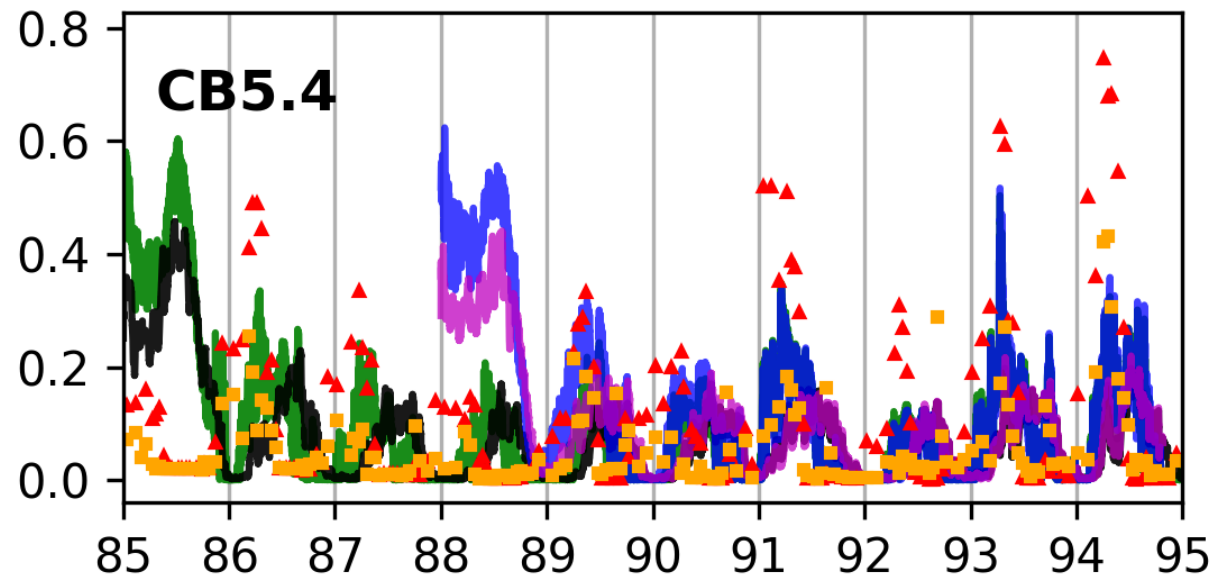

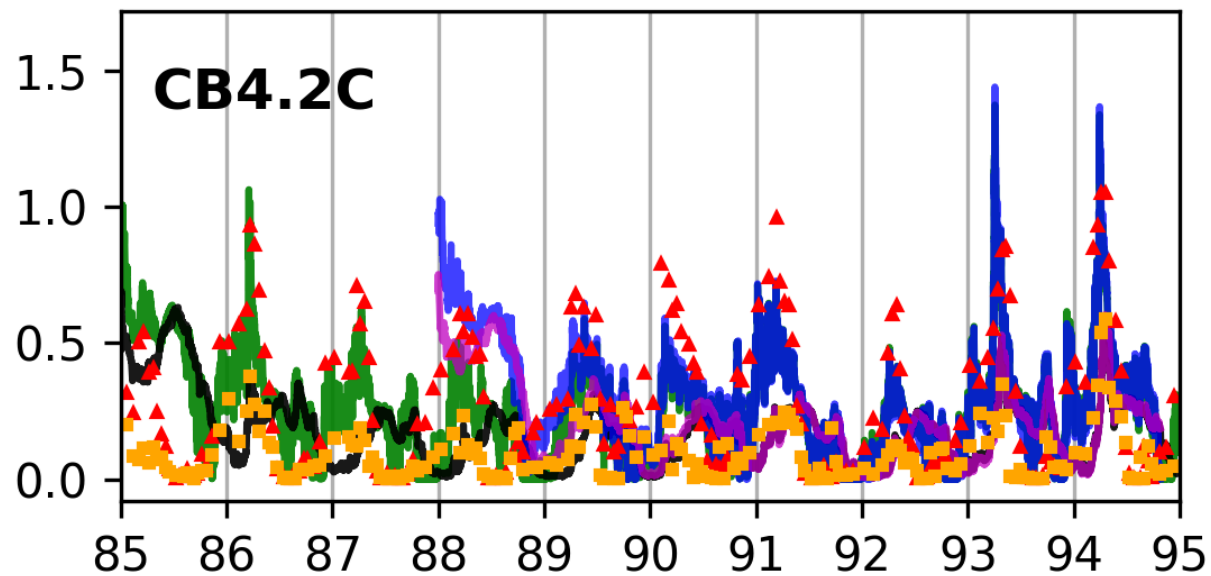

# Sensitivity Exps to ICM Initial Conditions: DO

Surface (RUN15a5) Surface (RUN15a6) Surface (OBS)  
Bottom (RUN15a5) Bottom (RUN15a6) Bottom (OBS)

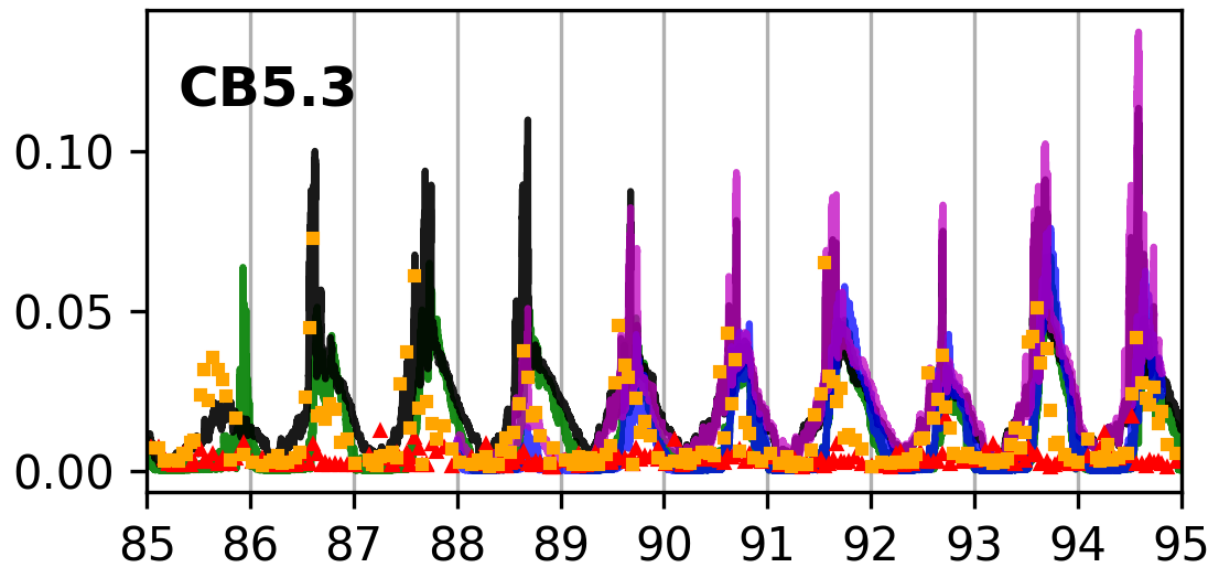

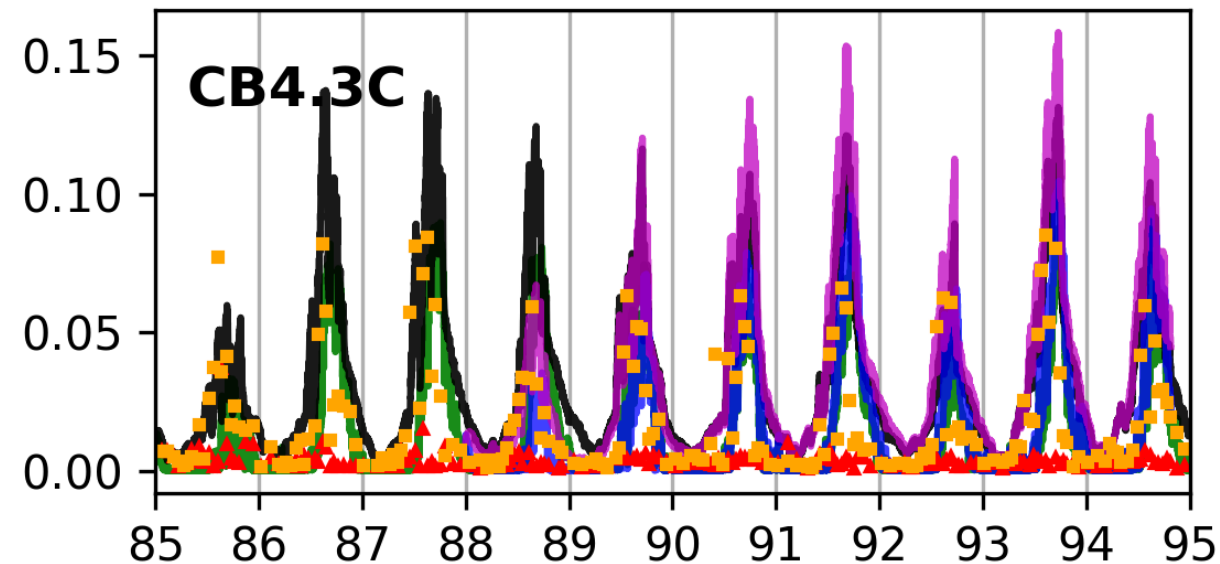

# Sensitivity Exps to ICM Initial Conditions: NO3

Surface (RUN15a5) Surface (RUN15a6) Surface (OBS)

Bottom (RUN15a5) Bottom (RUN15a6) Bottom (OBS)

# Sensitivity Exps to ICM Initial Conditions: sediment fluxes

## SLPD

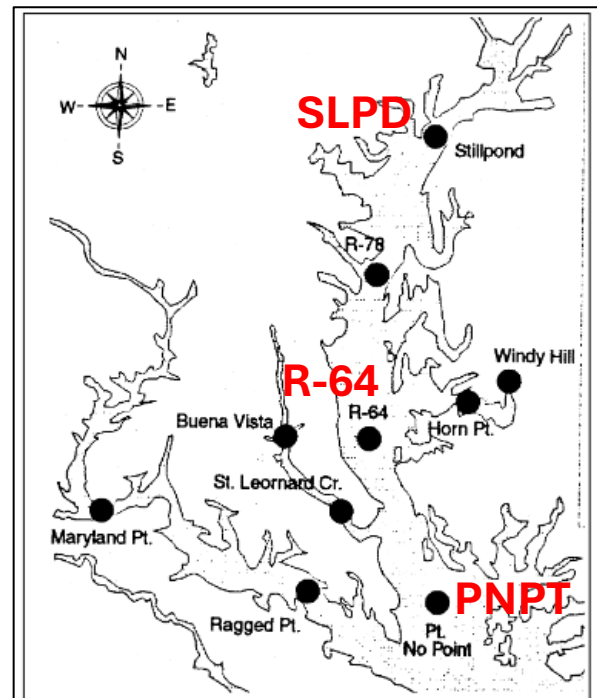

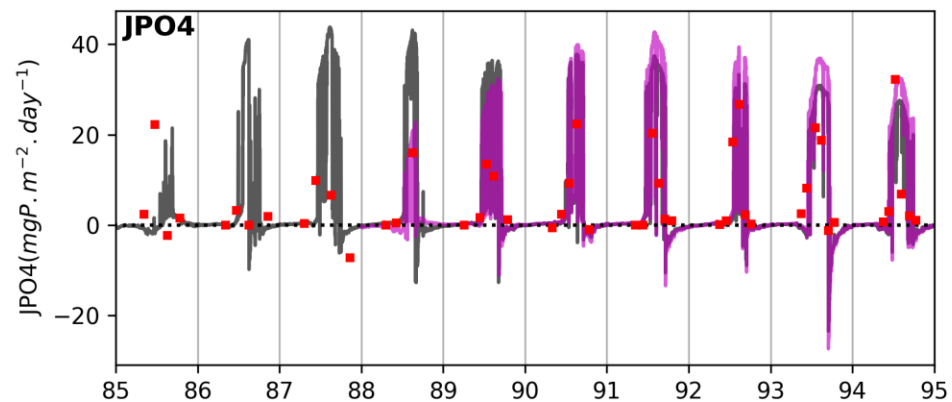

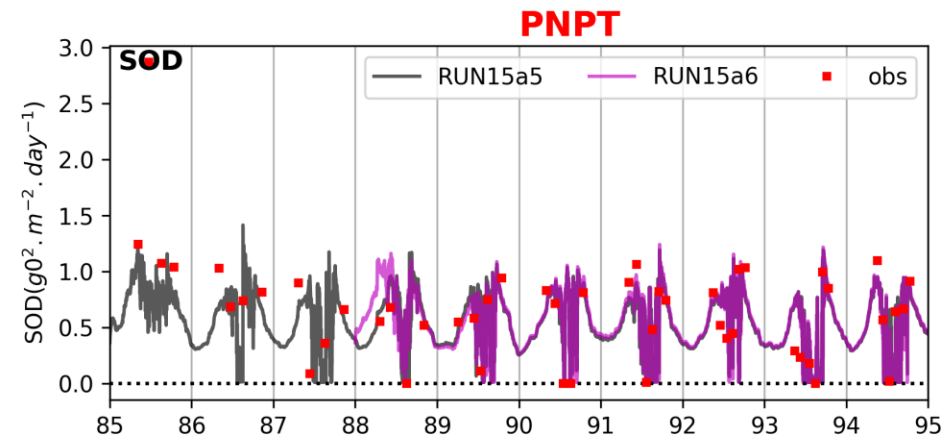

# Sensitivity Exps to ICM Initial Conditions: sediment fluxes

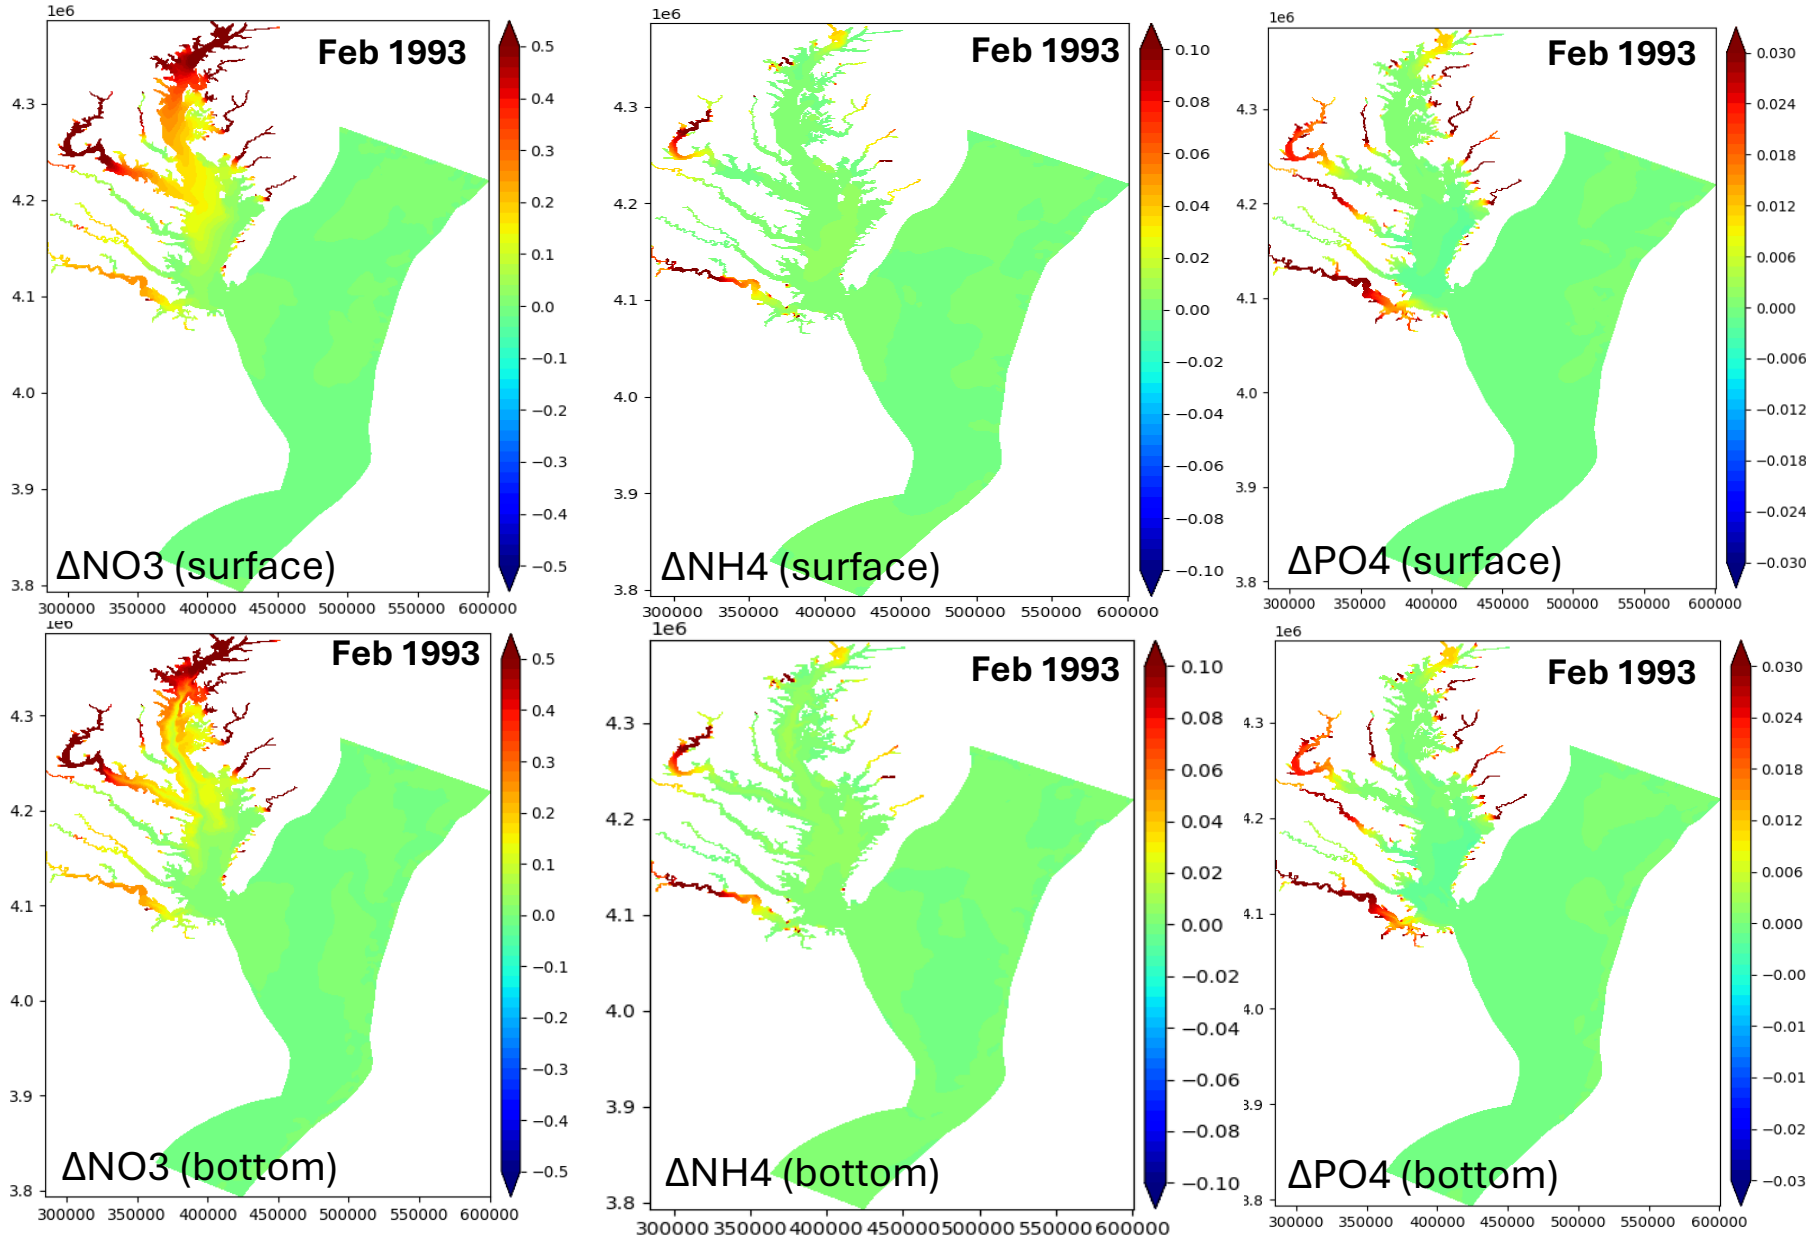

R-64

# Sensitivity Exps to ICM Initial Conditions: sediment fluxes

# Sensitivity Experiments to Riverine Nutrient Loadings: **First results**

**RUN14v26 (1.5 times):**  
higher riverine  $\text{NO}_3/\text{NH}_4/\text{PO}_4$

**RUN14v25 (0.5 times):**  
lower riverine  $\text{NO}_3/\text{NH}_4/\text{PO}_4$

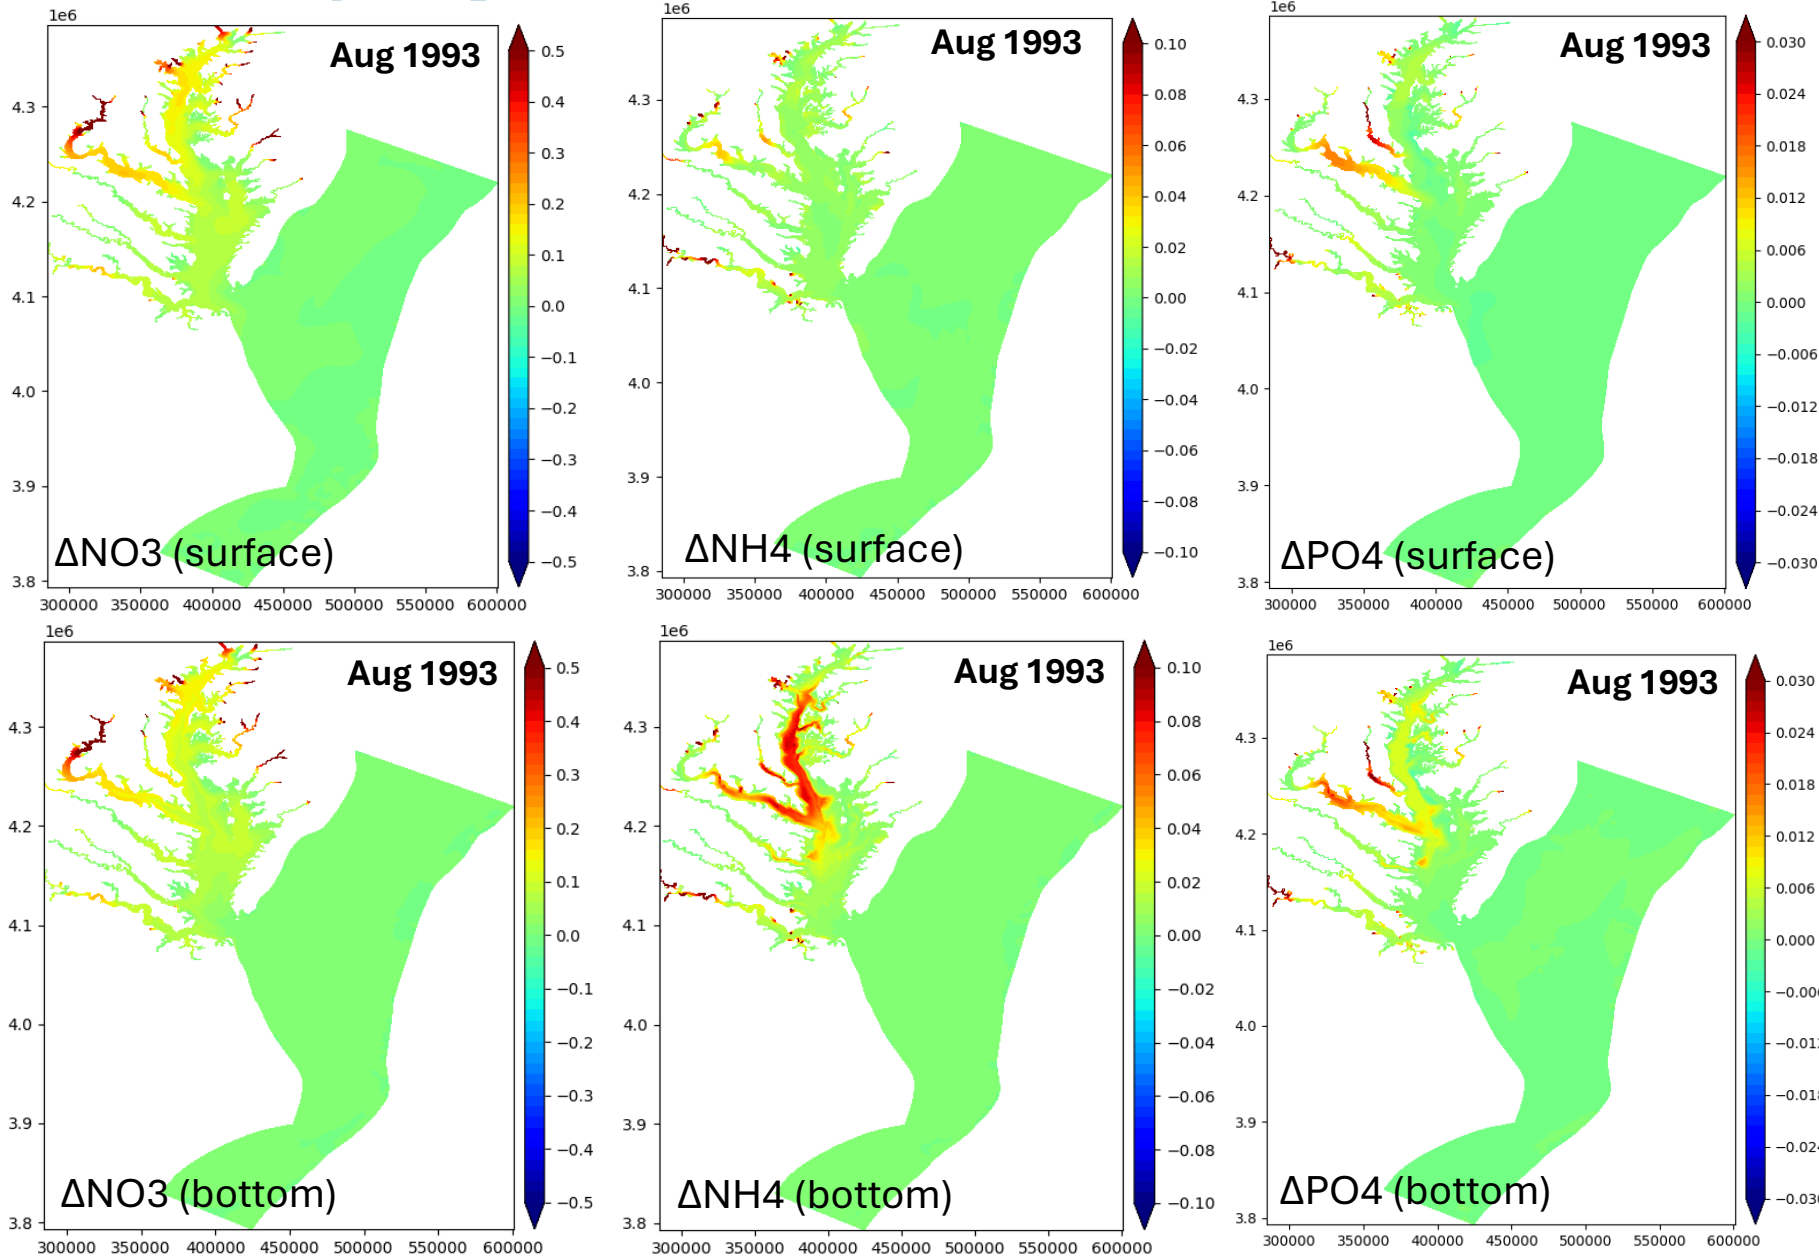

**In prep for WIP scenarios**

**RUN14v26 – base run**

**WINTER**

# Sensitivity Experiments to Riverine Nutrient Loadings

**RUN14v26 – base run**

**SUMMER**

- $\text{NO}_3$  is highly correlated to river flow, showing higher responses in winter and lower in summer.
- $\text{PO}_4$  &  $\text{NH}_4$  show quite similar responses, which are stronger in the bottom layer during summer.

# Sensitivity Exps to Riverine Nutrient Loadings: CHLA

☐ Surface CHLA increased in all seasons; Winter bottom CHLA peaks are higher

Surface CHLA (base run)

Surface CHLA (base run\*1.5)

Bottom CHLA (base run)

Bottom CHLA (base run\*1.5)

Higher winter diatom peaks

# Sensitivity Exps to Riverine Nutrient Loadings: DO

□ Surface DO increased, while bottom DO decreased with increased riverine nutrient loading.

Surface DO (base run)

Surface DO (base run\*1.5)

Bottom DO (base run)

Bottom DO (base run\*1.5)

Extended bottom hypoxic period in the mid Bay

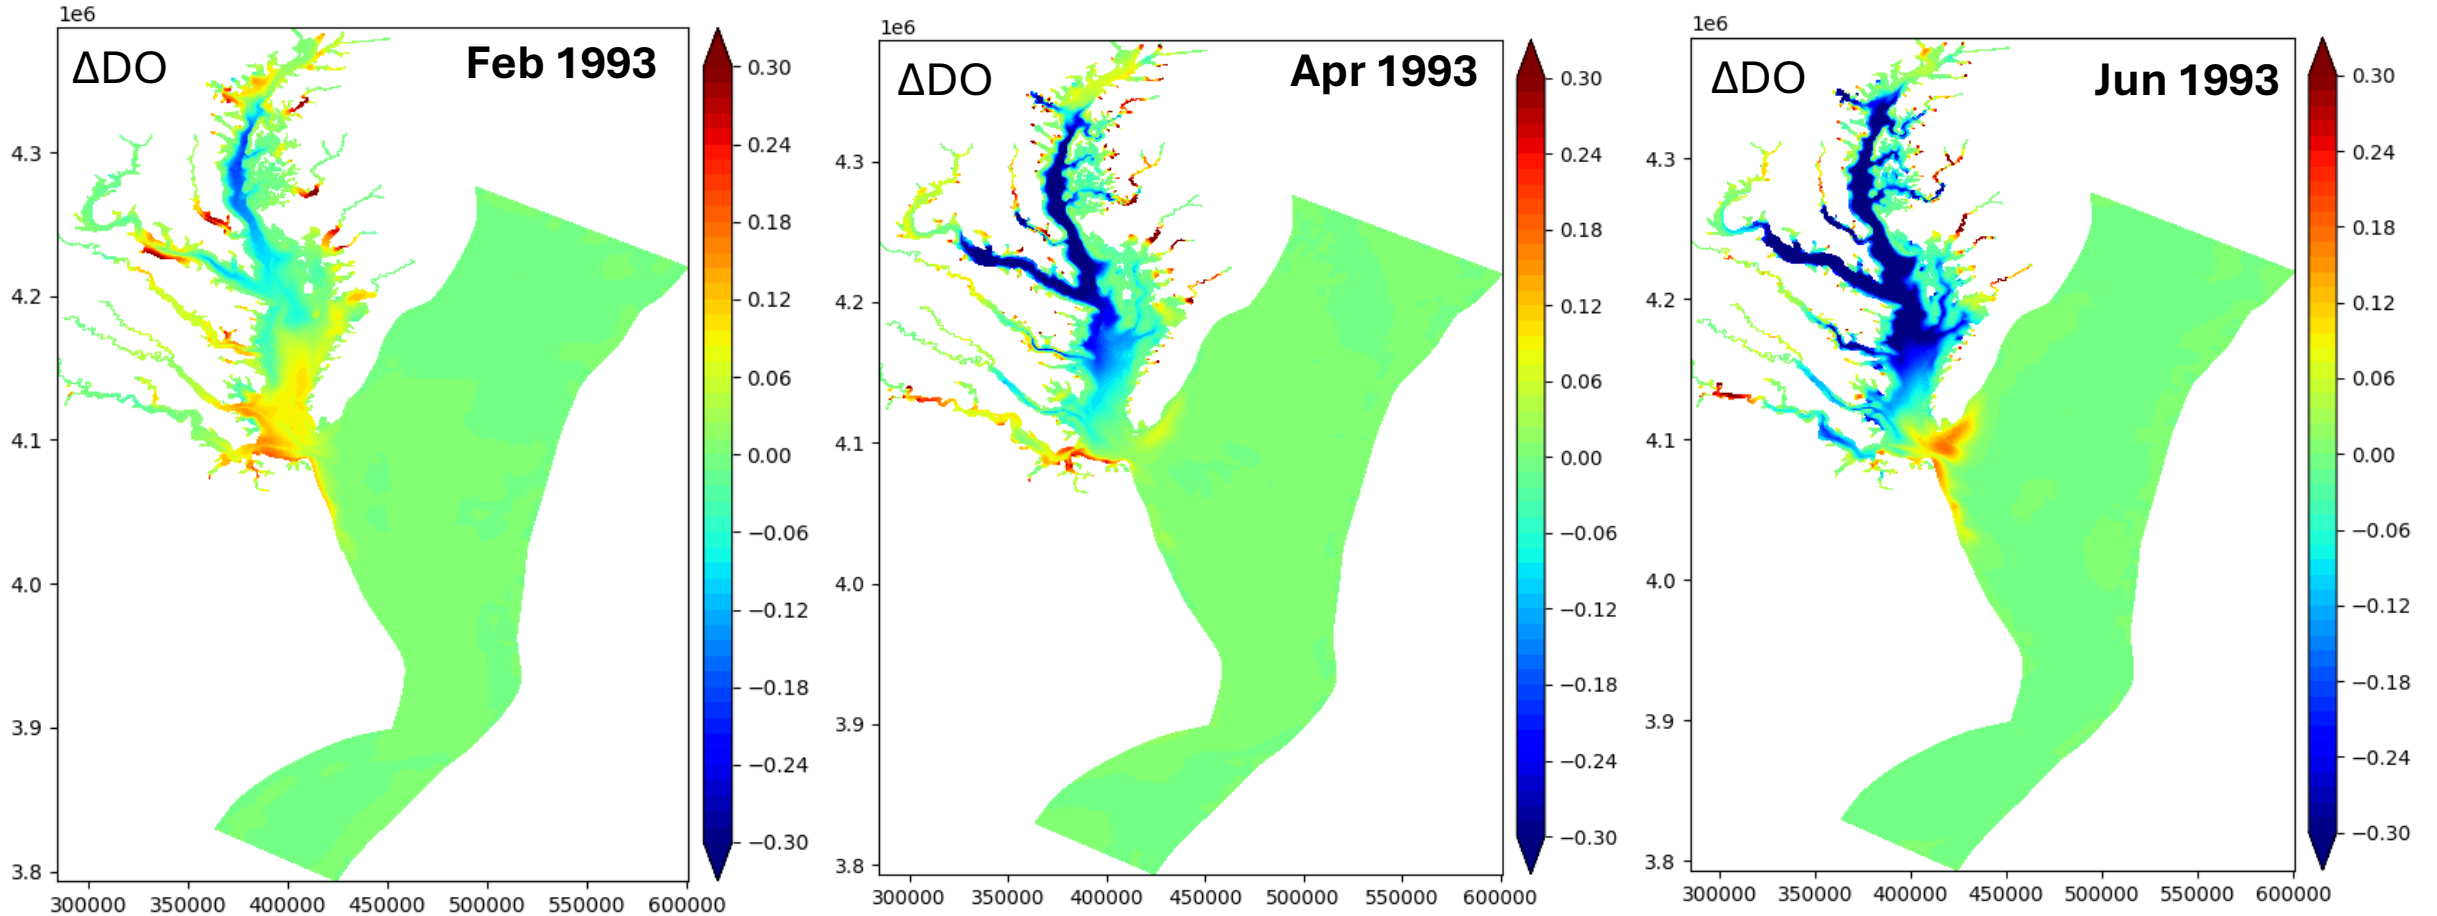

# Sensitivity Experiments to Riverine Nutrient Loadings: **surface** CHLA & DO

- Higher CHLA is directly responsible for higher DO in the surface layer of mid-Bay

# Sensitivity Experiments to Riverine Nutrient Loadings: **bottom DO**

- ❑ Bottom DO begins to decrease in the deep channel since early spring
- ❑ Higher CHLA leads to more DO consumption

# Summary

- ✓ Three-year spin-up may be sufficient for the MBM to reach equilibrium (ICM)
  - We may consider building a database of different initial conditions for each WIP scenario
  
- ✓ Preliminary results of sensitivity to nutrient inputs in prep for WIP scenarios
  - Higher nutrient loading increases surface DO but decreases bottom DO
  - NO<sub>3</sub> response is highly correlated to watershed loading
  - NH<sub>4</sub> & PO<sub>4</sub> changes may be more related to the phytoplankton response
  - Will continue to test with newer versions of WSM, MBM
