

James River Water Quality Model Refinement and Scenario Runs

Progress Report

Jian Shen

Virginia Institute of Marine Science

October 17, 2018

Outline

- Progress update
- Revised model calibration/verification
- Model scenario simulations
- Conclusions

Progress Update

- Update model calibration and verifications
 - Reviewed comments and feedbacks from preliminary model calibration results
 - Update model boundary condition from 2005-2013
 - Revised model calibration and verification
 - Revised model report for review
 - Conducted more sensitivity runs (open boundary, model parameters (half-saturation rates for N and P))
- Update watershed loading
 - Received updated Phase 6 baseline and used for model calibration
 - Received loadings for multiple point source reduction scenarios
 - Conduct model simulations for loading reduction scenarios

Update of model calibration and verification

- Model setup
 - Use CBP 3D model output as James River model open boundary condition (1991-2000, 2005-2013)
 - Use time-varying C:Chl-a ratio (Cerco and Noel, 2004)
 - Calibrate model using latest Phase 6 baseline condition (JCHLACAL20180808)

- Model parameters
 - Half-saturation rate for N and P

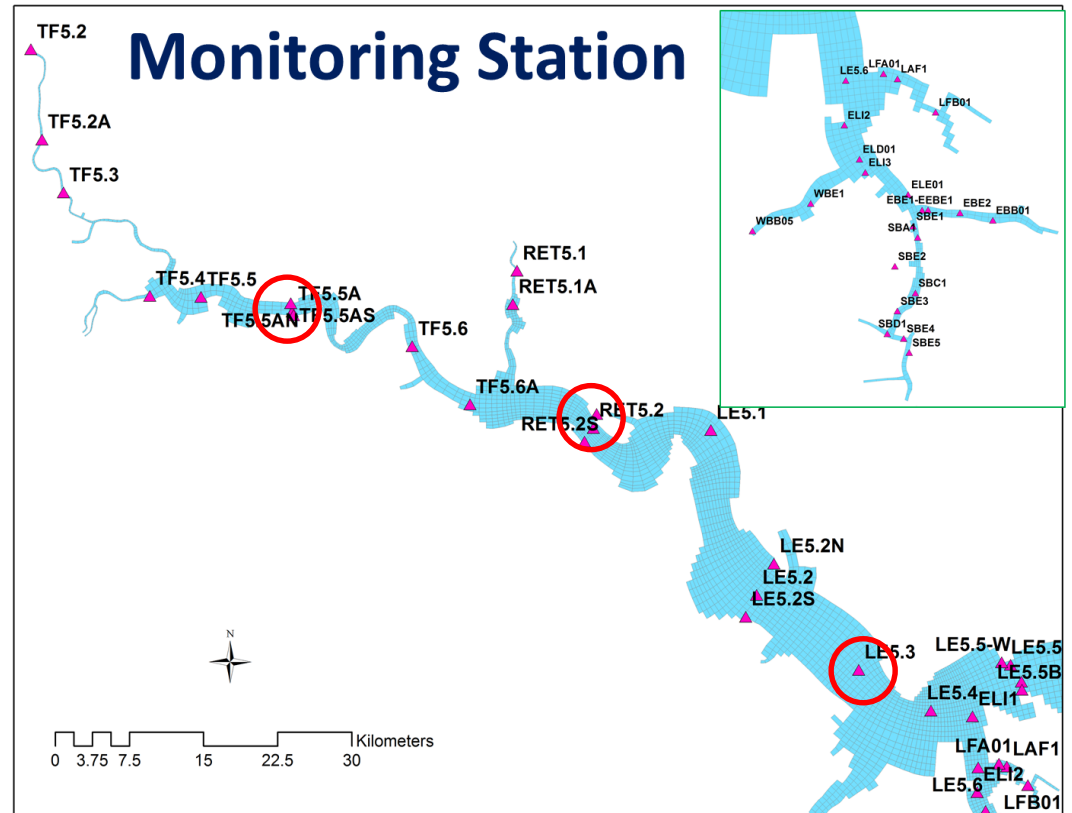

Model	N (mg/L)	P(mg/L)
Preliminary	0.015	0.0015
Final	0.02	0.0025

- Temperature related function

Examples of Model Calibration

- Tidal freshwater (TF5-5)
- Oligohaline (RET5-2)
- Mesohaline (EL5-3)

Model Calibration Results

TF5-3 (Surface)

TF5-4 (Surface)

TF5-5 (Surface)

TF5-5A (Surface)

TF5-6 (Surface)

Sensitivity Test of C:Chl-a Ratio

Sensitivity Test of C:Chl-a Ratio

10% decrease of Nitrogen at open boundary

10% decrease of phosphorus at open boundary

Change
TN half-saturation rate

Change
TP half-saturation rate

Parameter Uncertainty

- Conduct model experiments with 5% perturbation of model kinetic parameters. Compute sensitivity matrix and model uncertainty (inverse of sensitivity matrix)

Scenarios

- **2017 Watershed General Permit Waste Load Allocations**
- **Watershed Implementation Plan II (Mar. 2012) Level of Effort**
- **VAMWA Scenario "B+"**
- **VAMWA Scenario "C": Intermediate scenario**
- **VAMWA Scenario "D": Intermediate scenario**
- **VAMWA Scenario "B/D"**

Conclusions

- The model sensitivity tests indicate that a slight change of a model kinetic parameter will only result in minor changes of model calibration.
- Although different calibrations many result in differences in model-data comparison, it will not affect assessment based on the CBP's method to correct observations based on difference of baseline and reduction. It accounts for model uncertainty due to mismatch between model and observations.
- The use of time varying C:Chl-a ratio has large impact on Chl-a reduction compared to use of fix C:Chl-a
- Model is robust and is capable of conducting management scenarios.
